

Concept Note: Down-to-Earth Data Analysis Using Inverse Theory Hands-On

1. Introduction

Geophysical data analysis lies at the core of modern Earth sciences, enabling researchers to infer subsurface properties from indirect measurements. Inverse theory provides a rigorous mathematical framework for transforming observed geophysical data into meaningful interpretations. This concept note outlines a hands-on training module that integrates linear algebra, SVD, and factor analysis with examples from environmental science, paleontology and petrology and applications to global warming and current climate change.

2. Objectives

- Develop a conceptual and computational understanding of inverse problems in geophysics using Python and MatLab/R.
- Apply linear algebra and probability theory to model data relationships and solve over/under determined systems.
- Implement Singular Value Decomposition (SVD) for inverse problems and factor analysis to identify dominant patterns in multivariate geophysical datasets.
- Use the iLOSCAR code to invert paleogeographical data and compare with current global warming and climate change.

3. Topics Covered

3.1 Introduction to inverse theory: using observations to infer hidden properties.

Forward problem: Given a model (e.g., Earth layers), predict data.

Inverse problem: Given data, find the best model.

We write data as $\mathbf{d} = \mathbf{Gm}$, where $\mathbf{d}$ = observed data, $\mathbf{G}$ = sensitivity matrix (how model affects

data), **m** = model parameters (e.g., layer thickness, velocity)

3.2 Linear Algebra and Matrix Analysis foundation: Matrix operations, rank, null space, eigenvalues and eigenvectors. **Singular Value Decomposition (SVD)** breaks down the matrix **G** into simpler parts. Introduction to over- and under determined problems.

3.4. Probability & Bayes Theory: Posteriors, Likelihoods and Priors

3.5 Factor Analysis: SVD applied to rock chemistry data taken from a petrology database to deduce the number of the source rocks (called factors) and their composition from observations of the composition of the sediments (called samples)

3.6 Earth's Layers & Reflectivity: Solving the seismological problem of estimating the properties of an interface using measurements of reflection coefficients

3.7 Seismic Travel time Tomography: a widely used method of imaging the Earth's interior by using the travel times of waves propagating through the medium

3.8 Climate Change: analysis of sedimentary data records from the Permian epoch, real-world predictions from the IPCC using the iLOSCAR code, inferences for greenhouse effect

4. Tools & Software

Python: NumPy, SciPy, scikit-learn, **iLOSCAR:** For carbon cycle modeling (available via GitHub)

5. Expected Outcomes

- Proficiency in formulating and solving inverse problems in geophysics.
- Practical experience in applying SVD and factor analysis to real geoscience data.
- Improved interdisciplinary collaboration between mathematics, statistics, hydrology, petrology, environmental science, and geophysics.
